

External CDI processing demonstration notes.

1. OVERVIEW

The script **SetUpL11_5vCDIExternalProc.m** demonstrates Color Doppler Imaging with signal processing executed in an External Process Object by its associated MatLab "method" member function.

2. DIRECTORY CONTENTS

Files in this directory are listed in **contents.pdf**

3. USAGE

The script must be executed before it can be used by VSX:

```
>> SetUpL11_5vCDIExternalProc
```

```
>> VSX
```

```
L11-5vCDIExternalProc
```

This will bring up the standard Color Doppler Imaging GUI produced, for example, by the L11-5v Flash Doppler script. However, Doppler signal processing is computed in the MatLab function `cdiprocessing.m` rather than the Verasonics native C signal processing software. The GUI controls for Color Doppler Imaging will manage parameter settings in the function `cdiprocessing.m`.

Note: the wall filter coefficients computed by this function correspond to polynomial regression filters having stop-band order commensurate with ensemble length. This differs from the Verasonics native C version of the "regression" wall filter type, which has a fixed stop-band order.
